CONVNETS

Continued from previous slideset

Convolutional Network: Example

- Let's train a convnet with the famous MNIST dataset.
- MNIST consists of 60000 training and 10000 test images representing handwritten numbers from US mail.
- Each image is 28×28 pixels and there are 10 categories.
- Generally considered an easy problem: Logistic regression gives over 90% accuracy and convnet can reach (almost) 100%.
- However, 10 years ago, the state of the art error was still over 1%.

Convolutional Network: Example

```
# Training code (modified from mnist_cnn.py at
# Keras examples)
from keras.datasets import mnist
from keras.models import Sequential
from keras.layers.core import Dense, Dropout,
    Activation, Flatten
from keras.layers.convolutional import
    Convolution2D, MaxPooling2D

# We use the handwritten digit database "MNIST".
# 60000 training and 10000 test images of
# size 28x28
(X_train, y_train), (X_test, y_test) = mnist.
    load_data()

num_featmaps = 32 # This many filters per layer
num_classes = 10 # Digits 0,1,...,9
num_epochs = 50 # Show all samples 50 times
w, h = 5, 5 # Conv window size
```

```
model = Sequential()

# Layer 1: needs input_shape as well.
model.add(Convolution2D(num_featmaps, w, h,
    input_shape=(1, 28, 28),
    activation = 'relu'))

# Layer 2:
model.add(Convolution2D(num_featmaps, w, h,
    activation = 'relu'))
model.add(MaxPooling2D(pool_size=(2, 2)))
model.add(Dropout(0.25))

# Layer 3: dense layer with 128 nodes
# Flatten() vectorizes the data:
# 32x10x10 -> 3200
# (10x10 instead of 14x14 due to border effect)
model.add(Flatten())
model.add(Dense(128, activation = 'relu'))
model.add(Dropout(0.5))

# Layer 4: Last layer producing 10 outputs.
model.add(Dense(num_classes, activation='softmax'))

# Compile and train
model.compile(loss='categorical_crossentropy',
    optimizer='adadelta')
model.fit(X_train, Y_train, nb_epoch=100)
```

Convolutional Network: Training Log

- The code runs for about 5-10 minutes on a GPU.
- On a CPU, this would take 1-2 hours (1 epoch \approx 500 s)

```
Using gpu device 0: Tesla K40m
Using Theano backend.
Compiling model...
Model compilation took 0.1 minutes.
Training...
Train on 60000 samples, validate on 10000 samples
Epoch 1/10
60000/60000 [=====] - 31s - loss: 0.2193 - acc: 0.9322 - val_loss: 0.0519 - val_acc: 0.9835

Training (10 epochs) took 5.8 minutes.
```

Save and Load the Net

- The network can be saved to disk in two parts:
 - Network topology as JSON or YAML: `model.to_json()` or `model.to_yaml()`. The resulting string can be written to disk using `.write()` of a file object.
 - Coefficients are saved in HDF5 format using `model.save_weights()`. HDF5 is a serialization format similar to `.mat` or `.pkl`
- Alternatively, the net can be pickled, although this is not recommended.
- Read back to memory using `model_from_json` and `load_weights`

```
1 class_mode: categorical

```

*Part of network definition
in YAML format.*

Network Structure

- It is possible to look into the filters on the convolutional layers.

```
# First layer weights (shown on the right):  
weights = model.layers[0].get_weights()[0]
```

- The second layer is difficult to visualize, because the input is 32-dimensional:

```
# Zeroth layer weights:  
>>> model.layers[0].get_weights()[0].shape  
(32, 1, 5, 5)  
# First layer weights:  
>>> model.layers[1].get_weights()[0].shape  
(32, 32, 5, 5)
```

- The dense layer is the 5th (conv → conv → maxpool → dropout → flatten → dense).

```
# Fifth layer weights map 3200 inputs to 128 outputs.  
# This is actually a matrix multiplication.  
>>> model.layers[5].get_weights()[0].shape  
(3200, 128)
```

Network Activations

- The layer outputs are usually more interesting than the filters.
- These can be visualized as well.
- For details, see [Keras FAQ](#).
- Note: the outputs are actually grayscale; here in color only for better visualization.

Second Layer Activations

- On the next layer, the figures are downsampled to 12x12.
- This provides *spatial invariance*: The same activation results although the input would be slightly displaced.

DEEP LEARNING HIGHLIGHTS OF 2015-2016

*2015 was Full of Breakthroughs:
Let's See Some of Them*

TUT Research Example

- Automatic Car Type Detection from Picture: **Van, Bus, Truck or Normal Vehicle**
- The network recognizes the car type (4 classes) with 98% accuracy (13 000 images).

Components of the Network

```
1  % Pass image through 2 conv layers:
2
3  for layerIdx = 1 : 2
4
5      blob = convolve(blob, layers{layerIdx});
6      blob = maxpool(blob, 2);
7      blob = relu(blob);
8
9  end
10
11 % Pass image through 2 dense layers:
12
13 for layerIdx = 3 : 4
14
15     blob = layers{layerIdx} * blob;
16     blob = relu(blob);
17
18 end
19
20 % Pass image through the output layer:
21
22 blob = layers{end} * blob;
23 prediction = softmax(blob);
```

- **Convolution:** 5x5 window
- **Maxpooling:** 2x2 downsampling with the maximum
- **Relu:** $\max(x, 0)$
- **Matrix multiplication**
- **Softmax:**

$$[\sigma(\mathbf{x})]_k = \frac{\exp(x_k)}{\sum \exp(x_k)}$$

Object Localization

- **Object localization** attempts to find objects from the image together *with their location*.
- The most successful approaches are again deep net based.
- The key question is the speed: it is not possible to use the net at all positions at all scales.
- Instead, the framework relies on **object proposals**: A few hundred bounding boxes that may contain an object.
- Additionally, the process speeds up by processing all conv layers at once.

R-CNN

- The tool for ConvNet based object localization is R-CNN (*Regions with CNN*).
- History: CVPR2014: **R-CNN**; ICCV2015: **Fast R-CNN**; NIPS2015: **Faster R-CNN**
- Python implementation of the latter here:

<https://github.com/rbgirshick/py-faster-rcnn>

Recurrent Networks

- Recurrent networks process sequences of arbitrary length; *e.g.*,
 - Sequence \rightarrow sequence
 - Image \rightarrow sequence
 - Sequence \rightarrow class ID

Recurrent Networks

- Recurrent net consist of special nodes that remember past states.
- Each node receives 2 inputs: the data and the previous state.
- Most popular recurrent node type is *Long Short Term Memory* (LSTM) node.
- LSTM includes also *gates*, which can turn on/off the history and a few additional inputs.

Recurrent Networks

- An example of use is from our recent paper.
- We detect acoustic events within 61 categories.
- LSTM is particularly effective because it remembers the past events (or the context).
- In this case we used a *bidirectional* LSTM, which remembers also the future.
- BLSTM gives slight improvement over LSTM.

LSTM in Keras

- LSTM layers can be added to the model like any other layer type.
- This is an example for natural language modeling: *Can the network predict next symbol from the previous ones?*
- Accuracy is greatly improved from N-Gram etc.

```
model = Sequential()

model.add(LSTM(512, return_sequences=True,
               input_shape=(maxlen, len(symbols))))
model.add(Dropout(0.2))

model.add(LSTM(512, return_sequences=False))
model.add(Dropout(0.2))

model.add(Dense(len(symbols)))
model.add(Activation('softmax'))

model.compile(loss='categorical_crossentropy', optimizer='rmsprop')
```

Text Modeling

- The input to LSTM should be a sequence of vectors.
- For text modeling, we represent the characters as binary vectors:

```
from sklearn import preprocessing  
  
lb = preprocessing.LabelBinarizer()  
symbol_list = [c for c in 'hello world']  
lb.fit_transform(symbol_list)
```

	_	d	e	h	l	o	r	w
<i>Time</i> 	array([[0,	0,	0,	1,	0,	0,	0,	0],
	[0,	0,	1,	0,	0,	0,	0,	0],
	[0,	0,	0,	0,	1,	0,	0,	0],
	[0,	0,	0,	0,	1,	0,	0,	0],
	[0,	0,	0,	0,	0,	1,	0,	0],
	[1,	0,	0,	0,	0,	0,	0,	0],
	[0,	0,	0,	0,	0,	0,	0,	1],
	[0,	0,	0,	0,	0,	1,	0,	0],
	[0,	0,	0,	0,	0,	0,	1,	0],
	[0,	0,	0,	0,	1,	0,	0,	0],
	[0,	1,	0,	0,	0,	0,	0,	0]]

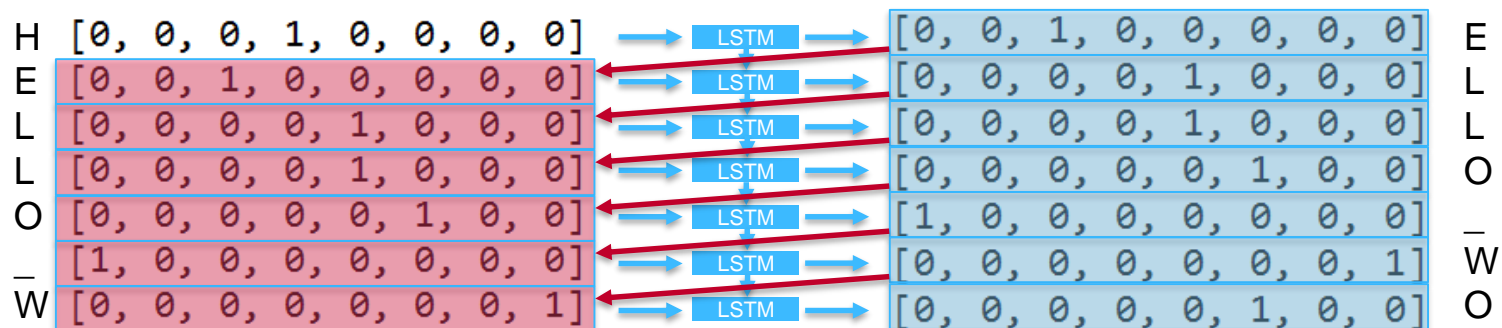

Text Modeling

- The prediction target for the LSTM net is simply the input delayed by one step.
- For example: we have shown the net symbols 'h', 'e', 'l', 'l', 'o', '_', 'w'.
- Then the network should predict 'o'.

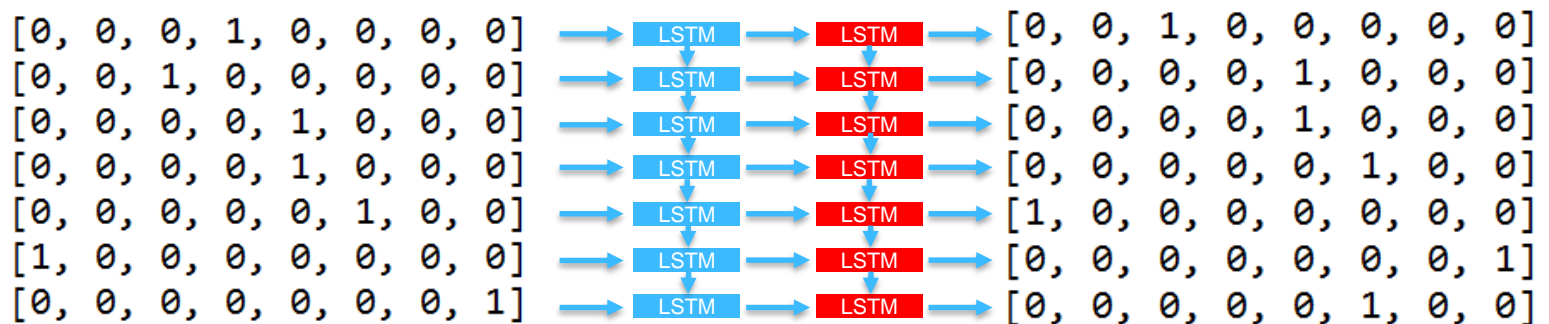

Text Modeling

- Trained LSTM can be used as a text generator.
- Show the first character, and set the predicted symbol as the next input.
- Randomize among the top scoring symbols to avoid static loops.

Many LSTM Layers

- A straightforward extension of LSTM is to use it in multiple layers (typically less than 5).
- Below is an example of two layered LSTM.
- Note: Each blue LSTM block is exactly the same with, e.g., 512 LSTM nodes. So is each red LSTM block.

LSTM Training

- LSTM net can be viewed as a very deep non-recurrent network.
- The LSTM net can be *unfolded* in time over a sequence of time steps.
- After unfolding, the normal gradient based learning rules apply.

Text Modeling Experiment

- Keras includes an example script:
https://github.com/fchollet/keras/blob/master/examples/lstm_text_generation.py
- Train a 2-layer LSTM (512 nodes each) by showing Nietzsche texts.
- A sequence of 600901 characters consisting of 59 symbols (uppercase, lowercase, special characters).

```
SUPPOSING that Truth is a woman--what then? Is there not ground  
for suspecting that all philosophers, in so far as they have been  
dogmatists, have failed to understand women--that the terrible  
seriousness and clumsy importunity with which they have usually paid  
their addresses to Truth, have been unskilled and unseemly methods for  
winning a woman? Certainly she has never allowed herself to be won
```

Text Modeling Experiment

- The training runs for a few hours on a Nvidia high end GPU (Tesla K40m).
- At start, the net knows only a few words, but picks up the vocabulary rather soon.
